At a certain laboratory results of *secret research* are thoroughly encrypted. A result of a single experiment is stored as an information of its completion:

'positive result', 'negative result', 'experiment failed' or 'experiment not completed'

The encrypted result constitutes a string of digits S, which may take one of the following forms:

- positive result
- negative result
- experiment failed
- experiment not completed

+	$S = 1$ or $S = 4$ or $S = 78$
-	$S = S35$
*	$S = 9S4$
?	$S = 190S$

(A sample result $S35$ means that if we add digits 35 from the right hand side to a digit sequence then we shall get the digit sequence corresponding to a failed experiment)

You are to write a program which decrypts given sequences of digits.

Input

A integer n stating the number of encrypted results and then consecutive n lines, each containing a sequence of digits given as ASCII strings.

Output

For each analysed sequence of digits the following lines should be sent to output (in separate lines):

+	for a positive result
-	for a negative result
*	for a failed experiment
?	for a not completed experiment

In case the analysed string does not determine the experiment result, a first match from the above list should be outputted.

Sample Input

```
4
78
7835
19078
944
```

try to match
+
-
*
any other case including 190S
--not completed

Sample Output

```
+
-
?
*
```
